## Code injection

#### Code Injection: Main idea

```
void func(char *arg1)
{
    char buffer[4];
    sprintf(buffer, arg1);
    ...
}
```

buffer

- (1) Load my own code into memory
- (2) Somehow get %eip to point to it

## Challenge 1 Loading code into memory

- It must be the machine code instructions (i.e., already compiled and ready to run)
- We have to be careful in how we construct it:
  - It can't contain any all-zero bytes
    - Otherwise, sprintf / gets / scanf / ... will stop copying
    - How could you write assembly to never contain a full zero byte?
  - It can't use the loader (we're injecting)

#### What code to run?

- Goal: general-purpose shell
  - Command-line prompt that gives attacker general access to the system
- The code to launch a shell is called **shellcode**

#### Shellcode

```
#include <stdio.h>
int main() {
   char *name[2];
   name[0] = "/bin/sh";
   name[1] = NULL;
   execve(name[0], name, NULL);
}
```

## **Assembly**

```
xorl %eax, %eax
pushl %eax
pushl $0x68732f2f
pushl $0x6e69622f
movl %esp,%ebx
pushl %eax
...
```

```
"\x31\xc0"
"\x50"
"\x68""//sh"
"\x68""/bin"
"\x89\xe3"
"\x50"
```

# Machine code

(Part of)
your
input

## Challenge 2 Getting injected code to run

- We can't insert a "jump into my code" instruction
- We don't know precisely where our code is

#### Recall

### Memory layout summary

#### Calling function:

- 1. Push arguments onto the stack (in reverse)
- 2. Push the return address, i.e., the address of the instruction you want run after control returns to you
- 3. Jump to the function's address

#### Called function:

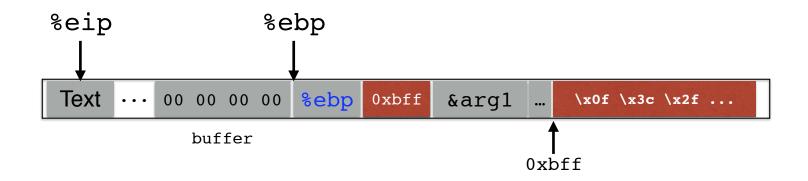

- 4. Push the old frame pointer onto the stack (%ebp)
- 5.Set frame pointer (%ebp) to where the end of the stack is right now (%esp)
- 6. Push local variables onto the stack

#### Returning function:

7. Reset the previous stack frame: %esp = %ebp. %ebp = (%ebp)

8.**Jump back to return address**: %eip = 4(%esp)

### Hijacking the saved %eip

But how do we know the address?

### Hijacking the saved %eip

What if we are wrong?

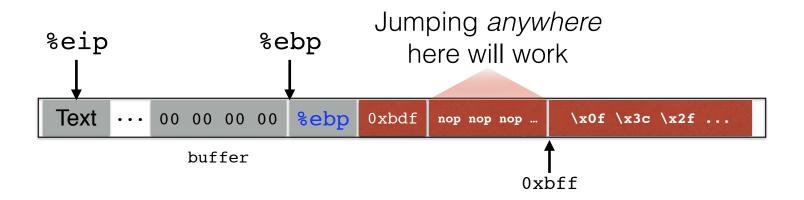

This is most likely data, so the CPU will panic (Invalid Instruction)

## Challenge 3 Finding the return address

- If we don't have access to the code, we don't know how far the buffer is from the saved %ebp
- One approach: just try a lot of different values!
  - Worst case scenario: it's a 32 (or 64) bit memory space, which means 2<sup>32</sup> (2<sup>64</sup>) possible answers
- Without address randomization (discussed later):
  - The stack always starts from the same fixed address
  - The stack will grow, but usually it doesn't grow very deeply (unless the code is heavily recursive)

#### Improving our chances: nop sleds

nop is a single-byte instruction
(just moves to the next instruction)

Now we improve our chances of guessing by a factor of #nops

### Putting it all together

But it has to be something;
we have to start writing wherever
the input to gets/etc. begins.

good
guess

Text ...

0xbdf nop nop nop ... \x0f \x3c \x2f ...

buffer

nop sled malicious code
